The International Observation Days (IOD) are an annual monitoring event for Bearded Vultures organised by the International Bearded Vulture Monitoring network (IBM). The monitoring action takes place in the first two weeks of October with a synchronous and coordinated survey on the focal day and covers large parts of the Alpine arc (since 2006), parts of the Massif Central (since 2012), the eastern part of the French Pyrenees (since 2016), several regions in Spain (since 2017), some selected sites in Bulgaria (since 2018) and the High Atlas (since 2019). The aim of this expanding network is to establish a Europe-wide monitoring of the Bearded Vulture population where time-synchronised observations on the focal day allow to make an approximate estimate of the population size and age class distribution. A monitoring action of this scale and the fact that birds are identified on an individual level whenever possible, is unique and generates baseline information for survival analyses and demographic modelling, which give valuable insight into the reintroduction progress. Furthermore, the number of participants during the IOD increases every year and thus the IOD represents a big public event that helps to increase awareness for the conservation of the Bearded Vulture as a flagship species.

1 Abstract

Despite the unfavourable weather situation in most of the Alpine range on this year's focal day (3.10.2020) more than 790 observers joined the IOD 2020 and reported 483 Bearded Vulture observations. Beside the 499 occupied observation sites some others were not accessible due to snowfall at even low altitudes on the focal day, which is why the monitoring event was locally postponed until later in the IOD period. Thus, the coordination work of the regional responsibilities of 15 IBM-partners and several associated organisations was all the more important because they know the local conditions and their monitoring teams. Thanks to their efforts and the support of numerous volunteers, ornithologists, park staff, hunters, gamekeepers and many more, the IOD, the largest international Bearded Vulture monitoring event, could still be carried out for the 15th time in a row.

In order to obtain a reliable Alpine population estimate, synchronous monitoring over a large part of the area is necessary to avoid double counting. However, due to limited access or poor visibility in many regions, the monitoring network could not be covered as in previous years. In addition, it must be assumed that fewer Bearded Vultures were observed flying at sites with bad weather, as a consequence of the unfavourable thermal conditions. Because of these limitations, no reliable estimate of the Alpine Bearded Vulture population or its age class distribution could be made in 2020. Nevertheless, in the Alps it was possible to identify 27 Bearded Vulture individuals with certainty, while a further 22 birds could be identified with slightly lower probability. These data provide important information on the life-history of these animals and can serve to calculate parameters for demographic modelling. Out of 38 GPS-tagged animals that sent data during the IOD period 2020, only 10 individuals could be identified. Thanks to GPS-tagging, we therefore understand how difficult it can be to identify animals and thus how valuable identification data is.

The Spanish IBM-partners profited from favourable weather conditions and estimated the Bearded Vulture population in Andalusia, Castilla y León, Castilla la Mancha, Murcia and Valencia with a minimal and maximal number of 28 and 45 Bearded Vultures, respectively. Furthermore, they were able to identify 20 Bearded Vulture individuals. In the French Pre-Pyrenees, the moderate weather situation allowed to estimate the local population at 8-14 individuals, while the IOD was cancelled in the Massif Central due to bad weather forecast. Same as in the last two years, no Bearded Vultures have been observed in Bulgaria where the species has been considered extinct since 1972.

The experiences of this year have confirmed that only a comprehensive monitoring network with synchronous observations allow to estimate the population size within a wide-ranging area such as the Alpine range. The IBM-network has been pursuing this goal since 1999 and in the course of time hundreds of Bearded Vulture enthusiasts have joined the network and are willing to support this project even under harsh weather conditions.

2 Key facts

Monitoring organisation

- 15 IBM-partners and several associated organisations coordinated the IOD 2020
- despite the harsh weather conditions 792 observers participated in Austria, Bulgaria, France, Germany, Italy, Spain and Switzerland
- 423 sites were occupied during the focal day (3.10.2020) another 76 during the IOD period
- weather situation at the observation sites: 36% good, 21% moderate and 43% unfavourable

Observation results

- 483 Bearded Vulture observations during the IOD period, 434 of them on the focal day 03.10.2020
- Bearded Vultures observed at 176 out of 499 sites (35%)
- observed age class distribution (number of observations)
 - adult (N = 278, 58%)
 - subadult (N = 13, 3%)
 - immature (N = 99, 20%)
 - juvenile (N = 43, 9%)
 - unknown (N = 50, 10%)

Age class distribution & populations estimates

- estimated age class distribution in the alps (individuals)
 - *no synchronous census due to bad weather*
- estimated number of Bearded Vulture individuals:
 - Alps: *no synchronous census due to bad weather*
 - Massif Central: *no IOD due to bad weather*
 - Pre-Pyrenees (FRA): 8-14
 - Spain¹: 28-45
 - Bulgaria: 0

Individual based data

- 27 (Alps) and 20 (Spain) individuals were identified
- 22 (Alps) individuals were probably identified
- GPS-data is available for 55 individuals during the IOD period 2020
- in the Alps 10 (~26%) of the 38 GPS-tagged individuals were identified by the observers

¹ Only for monitored parts (e.g. no survey in Spanish Pyrenees and other mountain ranges)

3 Preface

Due to bad weather conditions and snowfall down to lower altitudes on the focus day throughout the Alpine range, observations could only be carried out to a limited extent at many locations and had to be cancelled in others. Since synchronous observation and comprehensive monitoring was not possible, no estimates of population size can be derived for this year in most areas, especially in the Alps. Nevertheless, the observation of identified individuals provides valuable information and the commitment of many volunteers despite the harsh weather conditions shows the enthusiasm for the Bearded Vulture project and strengthens the monitoring community.

4 Methods

4.1 Organisation

The monitoring is coordinated and executed simultaneously over the four Alpine zones (eastern, central, north-western and southern Alps), in the Massif Central, in parts of the French Pyrenees, Spain and Bulgaria by local IBM-partners and associated organisations (**Figure 1**). This ultimately allows to gain information about Bearded Vulture presence thus avoiding/reducing the chance of double counts and allowing us to get the big picture of Bearded Vulture distribution.

In the previous years, monitoring was expanded towards the Pyrenees (department Aude in France) in order to reveal exchanges between the separated populations from the Alps and the Pyrenees. Since 2017, our Spanish colleagues (and new IBM-partner since 2019) organise the IOD within parts of Andalusia and Castilla y León and share their results with the IBM-network in order to contribute to get a wider picture about the Bearded Vulture population in western Europe. A new observer network is also establishing in the eastern parts of Europe in Bulgaria, where the *Green Balkans* participate at the IOD for the second time and thus raise awareness for the regionally extinct species.

As in the previous years, no IOD was organised on Corsica. Moreover, due to bad weather conditions, the IOD was not conducted in the Massif Central (FRA) and Vercors (FRA).

4.2 Time Period

The 2020's international survey was held between the 3rd and the 10th October with the focal day on Saturday 3rd of October. The buffer period of one week is chosen to allow more flexibility for areas where the weather conditions are not suitable on the focal day.

All dates are decided on mutual agreement among the IBM partners and take into account partner's availability, other ornithological appointments and the birds' reproductive behaviour (see [future dates](#)). The fact, that Bearded Vultures are active in nest building during October, makes this a suitable period to observe the birds and record possible new territories and breeding pairs.

4.3 Monitoring Area

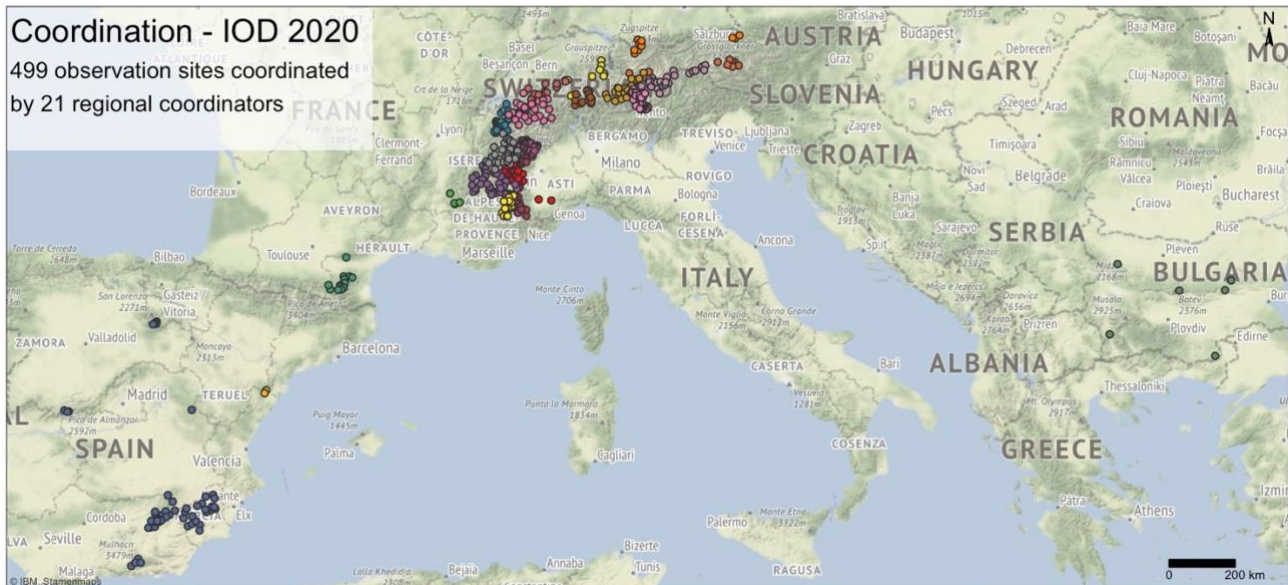

Figure 1. The IOD-monitoring area is regionally coordinated by 15 IBM-partners and associated organisations.

4.4 Data collection and observation protocol

Due to bad weather conditions the survey period varied considerably among regions and took place between 10:00 am and at least 15:00 pm. The teams are composed of one or more observers, at least one of them being experienced, equipped with binoculars and, depending on availability, telescope and camera. For each observation site and Bearded Vulture sighting the following information was recorded:

Observation site:

- Date and site occupancy (time)
- team/partner and observer names
- site name, address and coordinates
- weather conditions
- total number of observed Bearded Vultures
- presence/observation of other species

Bird observation:

- date
- time and duration of the observation
- age of the bird²
- bird name / hypothesis
- picture if possible

² In age classes: juvenile (1.cy), immature (2.-3.cy), subadult (4.-5.cy) adult (≥6.cy)

4.5 Data Analysis

Due to the bad weather conditions in the Alpine range, no population estimate can be made for this area this year. In the areas with suitable weather conditions, the procedure was the same as in previous years: All data is collected at the end of the day by the local administrators who will review the reported observations. The local administrators work in close cooperation with field assistants/observers and other nearby local administrators responsible for the surrounding monitoring areas. Based on for example individual markings, temporal overlap of the sightings, knowledge about known territorial birds and their juveniles that still remain in the area, they are able to critically assess the number of observations and judge to how many individual Bearded Vultures the IOD observations refer to. GPS-tagged birds that were not observed, are added to the estimate and also serve as a measure for detection probability.

The population estimate should only base on data from the focal day in order to avoid that individuals are observed and thus counted twice in two different regions. Individual identification is challenging and since it is not always possible to assess whether several observations have been made of the same individual, the final estimate includes a minimal and a maximal count number, namely accounting for a stricter versus a less conservative analysis.

4.6 Age classification

Per definition the IBM always uses calendar years (cy) for age specifications (**Table 1**).

Table 1. IBM-standard age classification.

Entry in the IBM (life stage)	Calendar year (cy)	Real age (years)		Life history event
		Jan-Feb	Mar-Dec	
juvenile (1. year)	1	-	0	<i>hatch</i>
immature (2. year)	2	0	1	<i>non-territorial</i>
immature (3. year)	3	1	2	<i>non-territorial</i>
subadult (4. year)	4	2	3	<i>non-territorial</i>
subadult (5. / 6. year)	5	3	4	<i>potential nesting</i>
adult (≥ 6. year)	6	4	5	<i>potential breeding</i>
adult (≥ 6. year)	≥7	5	≥6	<i>potential breeding</i>

5 Results and Discussion

5.1 Weather conditions

The overall weather situation was unfavourable in 2020 with 36% good, 21% mediocre and 43% bad weather situations at the observation sites (**Figure 2**). In 2019 only 1% of the sites reported unfavourable weather and therefore no comparison between the two years are possible. Unfavourable weather conditions decrease the detection probability of the individuals and should therefore be considered for the interpretation of the population estimates.

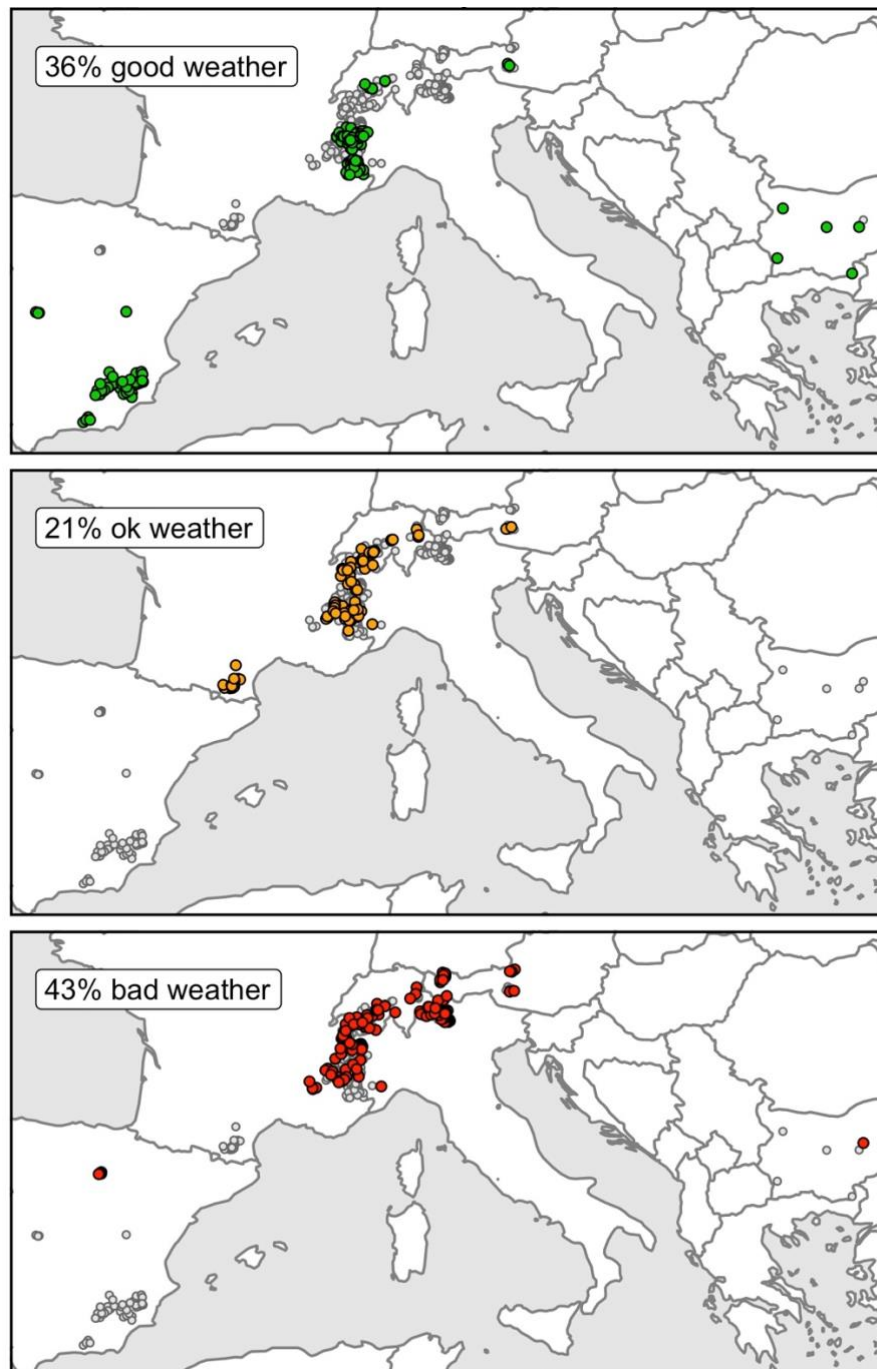

Figure 2. Weather conditions at the observations sites reported by the observers in the field during the IOD 2020. Only one third of the observers (36%) profited from good weather conditions and in some regions the survey had to be cancelled due snowfall, rain or poor visibility.

5.2 Observation data

In 2020, despite the unfavourable weather conditions a total of 792 observers have occupied 499 observation sites in the Alps, in the French Pyrenees (department “Aude”), parts of Spain as well as Bulgaria (**Figure 3 and Table 2**).

As in the previous years, the western regions of the Alps remain the most thoroughly surveyed areas together with the area of the Stelvio National Park in the North of Italy. With additional observation sites close to the Spanish border near the Pyrenees the IBM monitoring network plans to cover regions that might serve as a connection between the Bearded Vulture populations from the Alps and the Pyrenees. As it is known, that Bearded Vultures in Spain move between the mountainous areas in the South and the region of Castilla y León, Castilla-La Mancha and La Rioja in the North, the observer network has been expanded in these areas.

In the eastern part of Europe, in Bulgaria several observations sites were also occupied for the first time in 2018, even though so far, no Bearded Vultures are known to be present in this region. However, in the future this region could serve as a stepping-stone area between the Alpine and Greek Bearded Vulture population and to establish an observer network in this area thus makes sense in the long-term perspective.

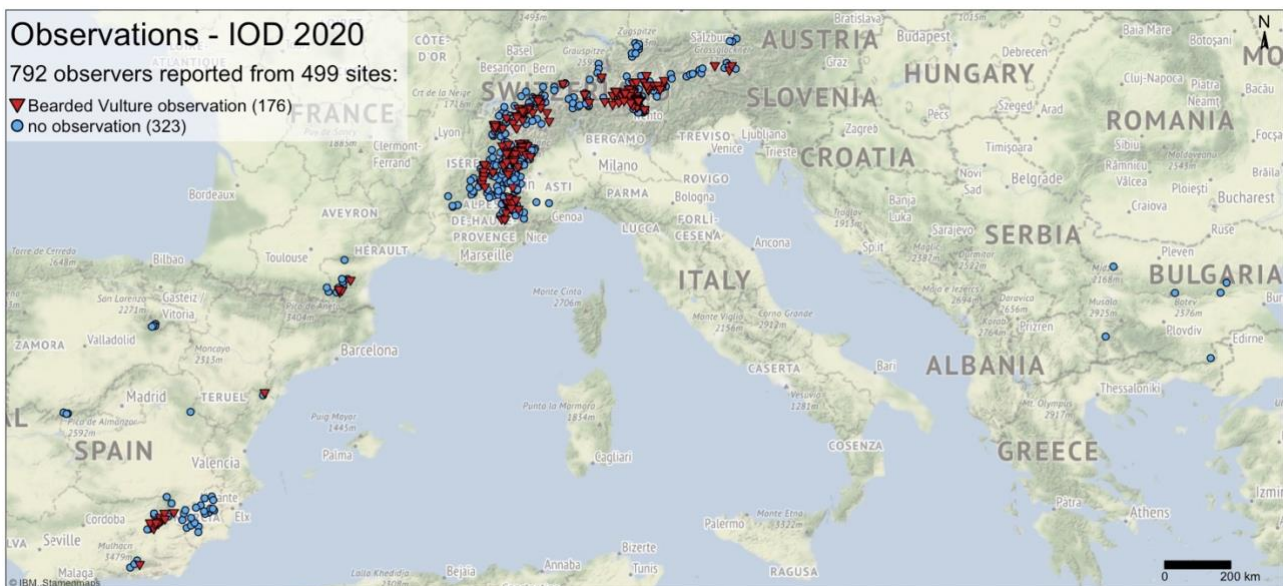

Figure 3. Distribution of all 499 observation sites during the IOD 2020 in Europe. Red triangles depict those sites where Bearded Vultures have been observed at least once during the IOD period 3rd-10th of October 2020 (N=176) while no observations have been reported from sites marked with a blue dot (N=323).

5.3 Telemetry data

5.3.1 IBM-monitoring area

During the IOD-period GPS-data of 55 Bearded Vultures with satellite tags have been retrieved in the Alpine range, the Massif Central, the Pyrenees, north-eastern Spain and Corsica³ (**Figure 4**). Although this data is not part of the IOD, this information is collected as representative of their positions and to detect areas of monitoring deficiencies. Some of these birds still show their individual marking patterns (bleached feathers) and can therefore be identified by observers. Exceptions are the wild-born birds which have been GPS-tagged but not marked by bleaching their feathers.

GPS-data can serve as an indicator to assess the risk of double counting of individuals. The wide range movement patterns of some birds (**Figure 4**) underline the importance of using only observational data from a narrow period (focal day) for population estimation to avoid double counting.

³ No IOD was organized on Corsica in 2020.

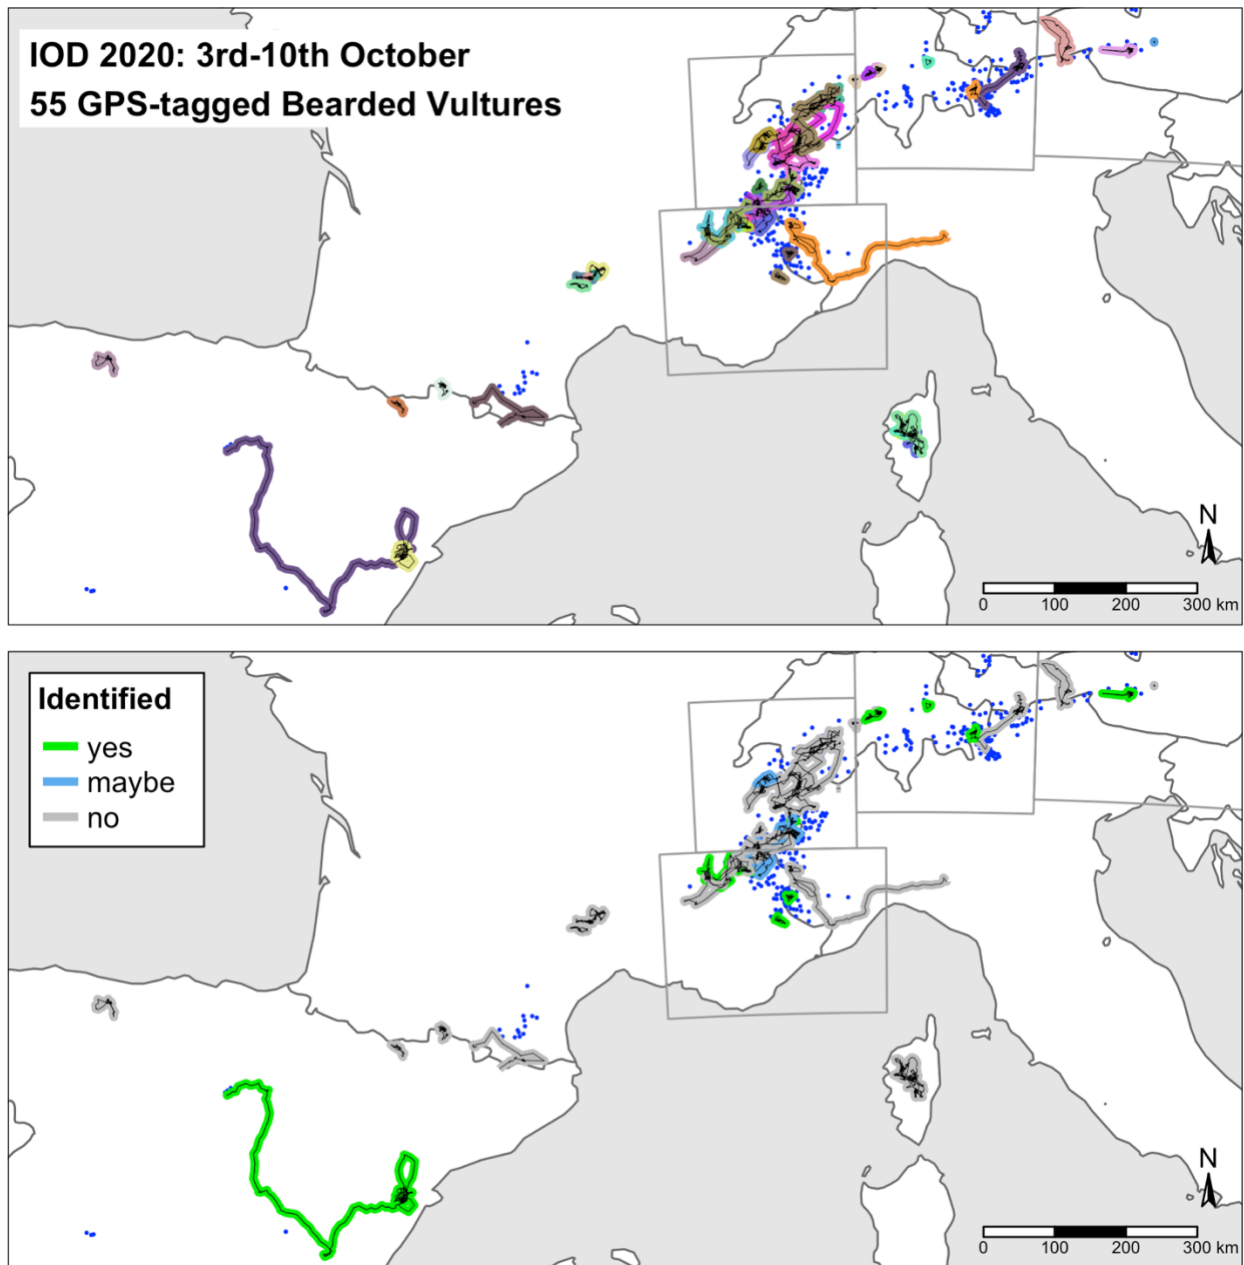

Figure 4. 55 GPS-tagged Bearded Vultures during the IOD periode. Blue dots = occupied observation sites.

5.3.2 Alpine range

During this year's IOD, GPS-data in the Alpine range was available from 35 out of 38 GPS-tagged birds during the IOD period and on the focal day (3.10.2020). No data was available from Mison (W230), Noel-Leya (BG797) and Ewolina (BG838) on the focal day. Out of the 38 GPS-tagged birds 10 individuals could be sighted and identified, while 5 birds were identified with some uncertainty by observers. In 2020 38% of the GPS-tagged birds have been sighted and identified, similar compared to 2019 (35%).

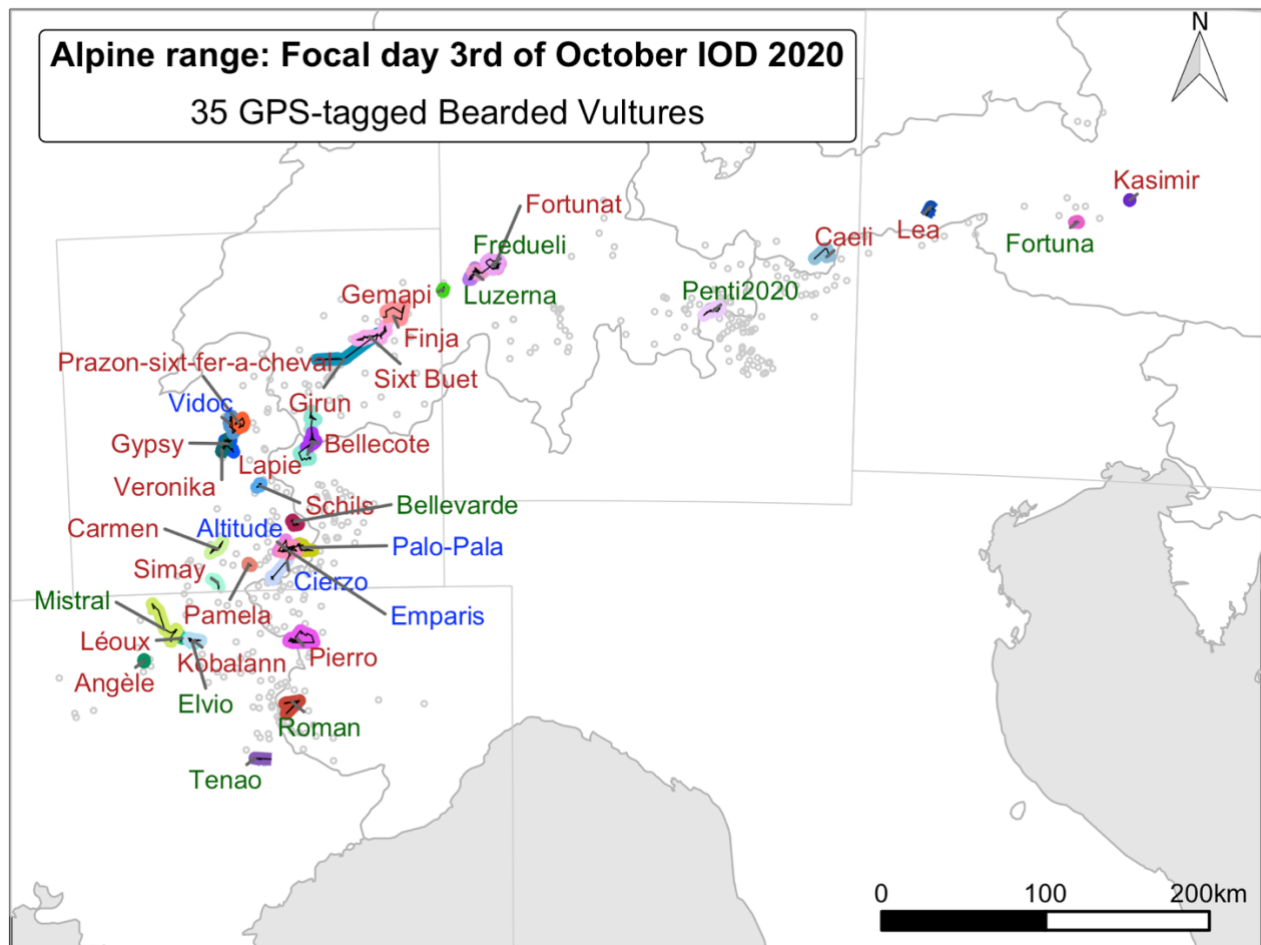

Figure 5. Positions of 35 Bearded Vultures tagged with GPS transmitters that were present in the Alpine range during the focal day (03.10.2020). Observation sites that were occupied during the IOD-period are marked with grey circles. During the IOD-period 10 birds have been identified (green labels), 5 birds have been identified with high probability (blue labels) and 23 birds couldn't be identified (red labels).

Table 4. 55 birds, 28 males and 23 females, with active GPS-tag during the IOD periode 2020. No IOD was organised in Corsica and the Massif Central in 2020.

5.4 Individual based data

During the IOD 2020 period 27 individuals have been identified with high probability in the Alpine range. 2 of them in the eastern Alps, 13 in the central Alps, 1 in the north-western Alps, 11 in the south-western Alps and 20 in Spain. In the Alpine range, another 22 birds were identified with uncertainty and these "potentially" identified birds are marked as "maybe identified" in

Table 5 & Table 6. Such individual based monitoring is only possible due to the international collaboration, information exchange and the coordination of marking patterns within the international Bearded Vulture monitoring network.

Table 5. 49 Bearded Vultures that were identified (22 of them with some uncertainty = maybe identified) in the Alpine range during the IOD 2020 grouped by the region where they have been observed.

5.5 Spatial distribution of age groups

From 499 sites 483 Bearded Vulture sightings have been recorded during the whole period, 434 during the focal day (**Table 3**).

In terms of reintroduction and resettlement of a species like the Bearded Vulture, it is of interest to gain a picture of the spatial distribution of different age classes. In particular, the presence of sexually mature adult birds can be an indicator for the formation of new reproductive units in the periphery of the species' distribution.

The following figures (**Figure 6 - Figure 12**) show the presence of Bearded Vultures subdivided in the two age groups adult and non-adult (juvenile, immature, subadult) at the regional level and give a more detailed overview on the Bearded Vulture distribution during the whole observation period. Each symbol on the map represents the position of an observation site.

5.5.1 Alpine range

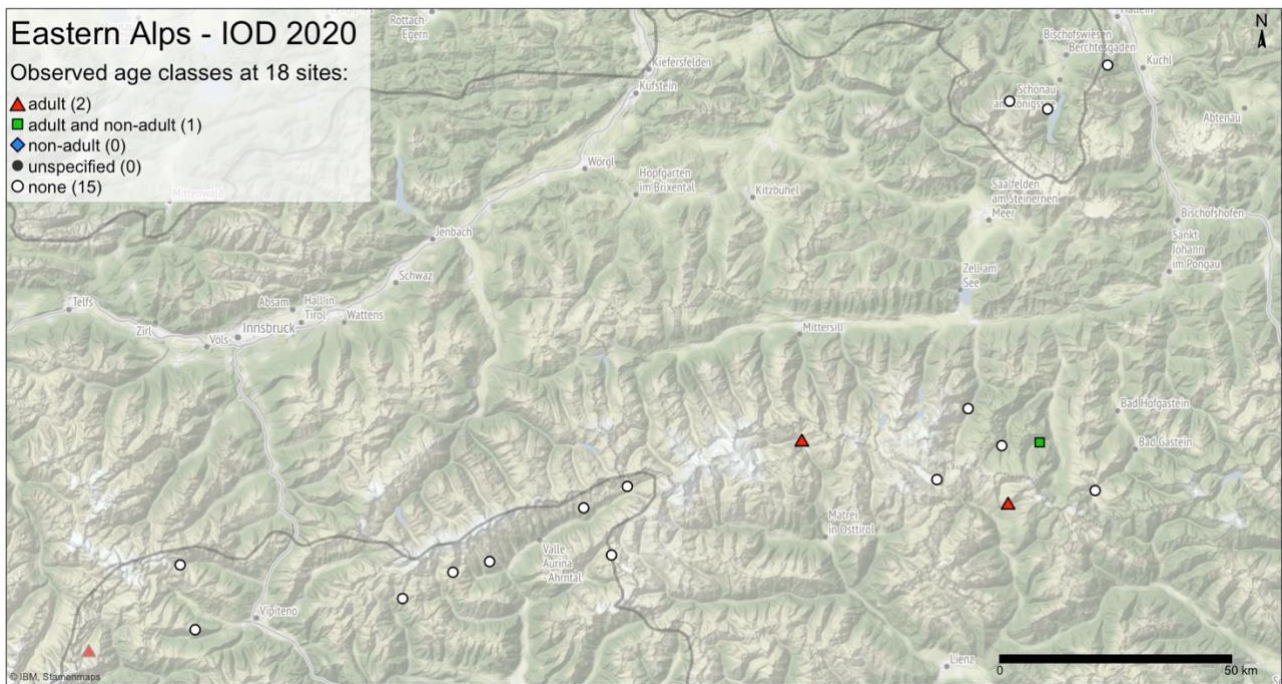

Figure 6. Age class distribution observed at 18 sites in the Eastern Alps during the IOD 2020.

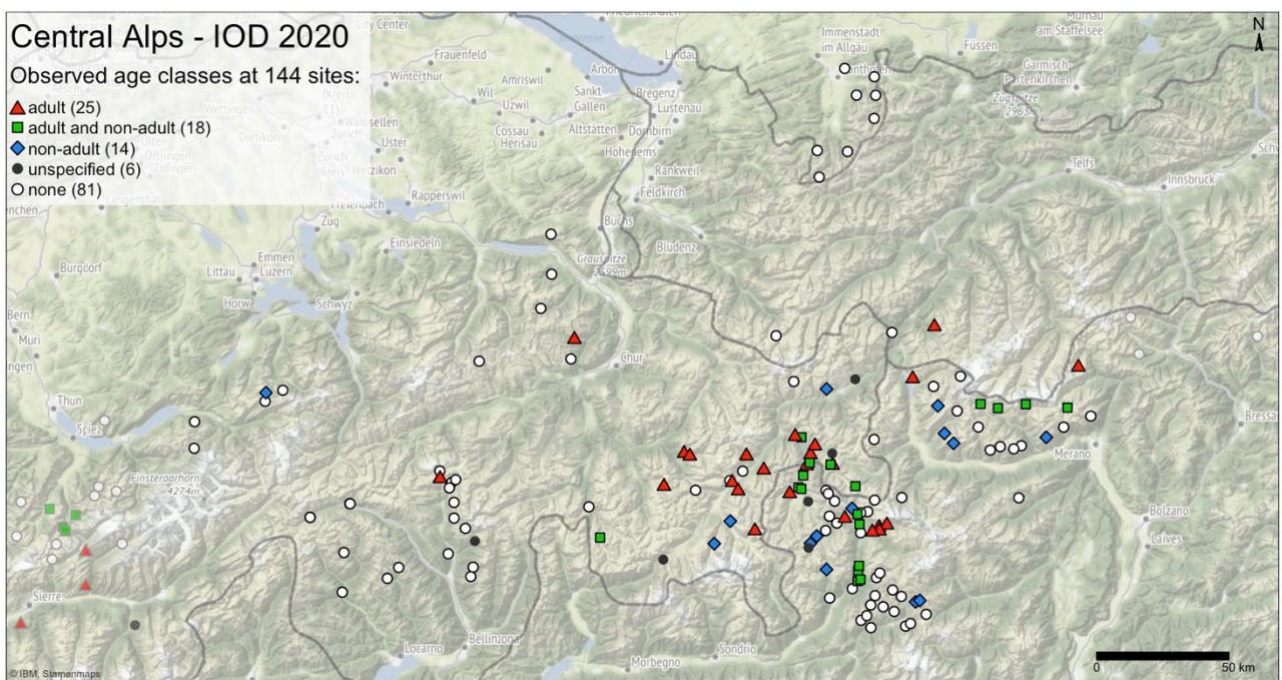

Figure 7. Age class distribution observed at 144 sites in the Central Alps during the IOD 2020.

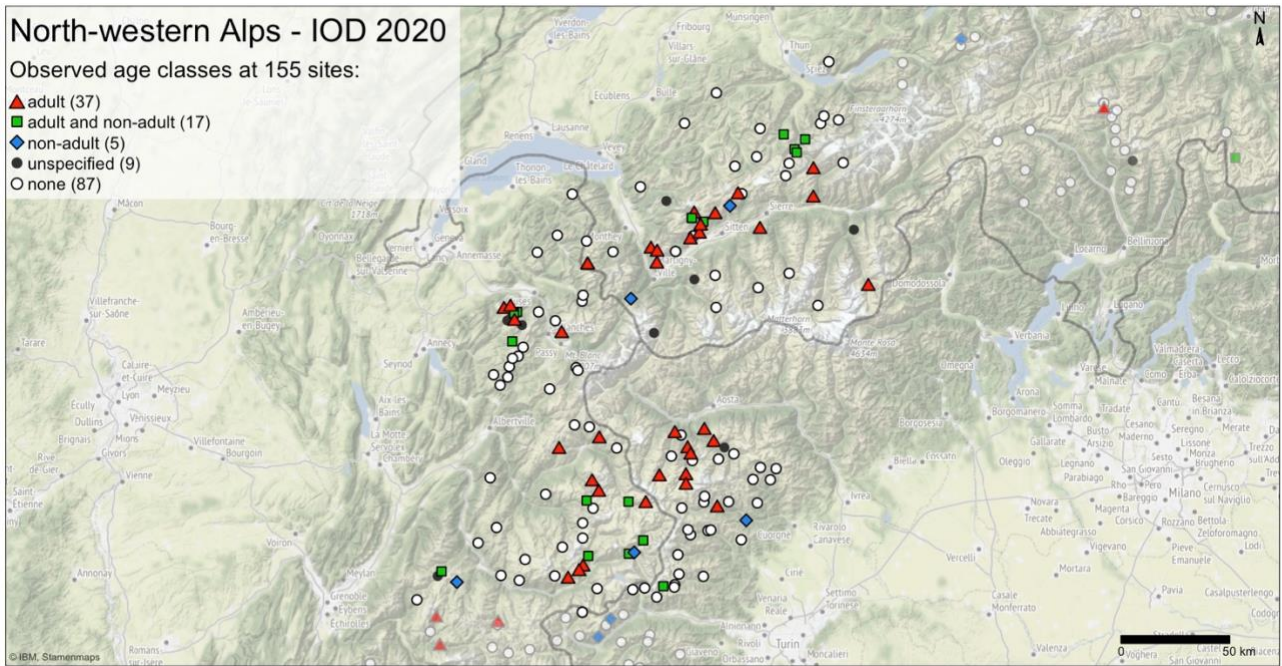

Figure 8. Age class distribution observed at 155 sites in the north-western Alps during the IOD 2020.

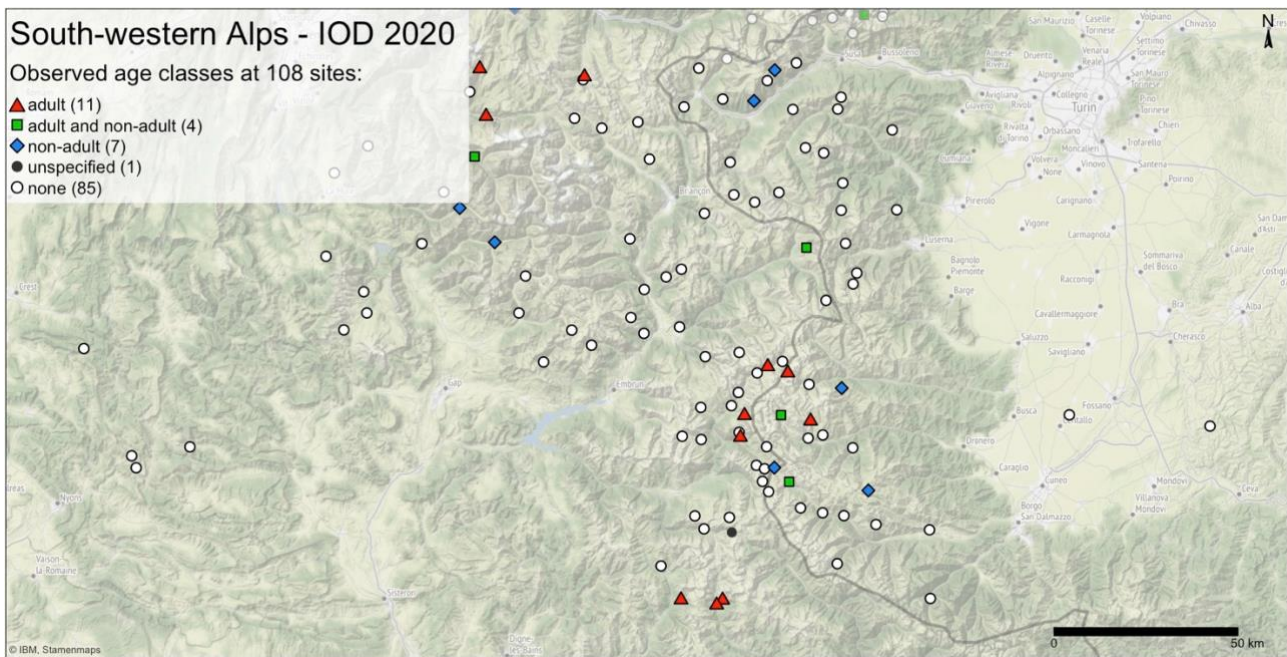

Figure 9. Age class distribution observed at 108 sites in the north-western Alps during the IOD 2020.

5.5.2 Massif Central & French Pre-Pyrenees

Figure 10. Age class distribution observed at 13 sites in the region between the Massif Central and the french Pyrenees during the IOD 2020.

5.5.3 Spain (without Pyrenees)

Figure 11. Age class distribution observed at 55 sites in Spain during the IOD 2020.

5.5.4 Bulgaria

Figure 12. Age class distribution observed at 6 sites in Bulgaria during the IOD 2020.

6 Outlook 2021

Before 2015, an Europe wide alternative date was set, which was abandoned due to difficulties in organising and decision for postponement. However, in weather situations like in 2020, it would have been very helpful to have this second date. Therefore, from 2021 onwards, a focal day, observation period and second date are agreed and set. It will be a joint selection if the first focal day can be respected or if the full IOD has to be postponed.

Period 2nd - 9th of October 2021

Focal day 1: Sat 2nd of October 2021.

Focal day 2: Sat 9th of October 2021 (bad weather alternative)

Even though a period of one week was chosen for public communication, we would like to stress the importance of focused observation intensity. Observations can be cumulated only within the core period. Therefore, **the count by specialists and volunteers on observation posts shall be carried out only during the focal day.**

The focal time for the count starts at 10 am to at least 3 pm.
